

The Case for the Metaverse Browser

Metaverse Standards Forum | RP1

metaverse-standards.org/open-metaverse-browser-initiative

omb.wiki

Metaverse Terminology

The metaverse combines the power of spatial computing with the connectivity of the web

The metaverse is the 3D evolution of the World Wide Web

The web was built for pages

Show a warehouse inventory report

SKU	Description	Location	Qty On Hand
TR-2301	Motor Assembly	Aisle 12B	58
DC-8873	Sensor Module	Aisle 28B	34
AA-1127	Control Unit	Aisle 14B	12
FS-3345	Power Supply	Aisle 24A	27
CM-7710	Connector Pack	Aisle 34C	73

The metaverse is built for **places**

The world is going spatial

Every era of computing had its defining hardware

Each generation of hardware enabled a defining experience

AR hardware is racing to replace mobile phones

Pioneers in AR Hardware

- Meta
- Snapchat
- Samsung
- Xreal
- RayNeo
- Even Realities
- & more

While mobile phones can handle spatial computing and physical AI today, AR glasses are designed to enable the optimal spatial experience

We need a global platform to deliver spatial services

Both AI and Humans are both going to need to connect to the real world

AR glasses
AI/Smart glasses
VR headsets
AI Wearables

Smart Homes
IoT Devices
AI Assistants
Digital Twins

Physical AI
Robotics
Autonomous Vehicles

Citizen services
Smart Cities
Traffic Routing

Spatial services will connect you to the world – not apps

Every device that operates in the physical world needs to discover and connect to services around it

The world is looking for how to
evolve the web to include
metaverse infrastructure

The web is the only platform with the needed
global reach **and is based on** open standards

Millions of **services** will run across the Metaverse

Airports

Navigation | Flights Status
Dining | Baggage Claim

Manufacturing

Machine Health | Quality
Control | Safety | Maintenance

Energy

Remote Expert | Pipeline Data
3D Schematics | Hazard Zones

Smart City

Transit | Parking
Events | Air Quality

Education

Lectures | Research
Campus Dining | Navigation

● Joining from Seattle
Connected

Houston we have a problem!

The web was not designed for spatial browsing

It's not a WebXR problem, it is a web problem

WebXR works for:

Single-origin apps

JavaScript → Canvas → one app, one origin.

DOM and iFrames limit WebXR:

Can't easily dynamically connect to multiple discovered new services

Can't discover and load scenes and services based on proximity

Can't securely compose multi-origin scenes

Can't enable real-time spatial co-presence

Metaverse walled gardens exist largely because of the web's limitations

Hardware and software are vertically siloed

Each device ships it's own isolated app ecosystem

No network effect or interoperability

Content and users are trapped inside each platform

Everyone reinvents their own tooling, no shared ecosystem

Every platform, experience, and space is rebuilt from scratch

Unable to self-host spatial content

Can't host content the same way you host a website on your own server

We are in the 'AOL/CompuServe' phase of the metaverse

Two worlds, neither complete

Each solves part of the problem. Neither delivers spatial browsing.

The Web (Browsing, not spatial)

Restricted performance

Javascript and V8 are not fast enough for high-performance real-time 3D

Restricted memory

Not enough for large or complex spatial scenes

Restricted device access

Camera, GPS, microphone beyond permission walls

Restricted storage

Cannot reliably store data locally through a web session

Native Engines (Unity/Unreal) (Spatial, but not browsing)

Requires compilation per device

Separate builds for each target platform

Updates are slow and manual

Must contact each device to update and reinstall

Not interoperable

Content built in one engine won't work in another

Not designed to stream

Large packages built to install and run locally

To get spatial browsing, you need both sets of capabilities in one place.

The entire industry is fragmented

No interoperability. No unified access. Maximum friction.

- Every vendor runs its own maps, SDK, and data silo
- Robotics, security, IoT, and digital twins all operate independently of each other
- No System connects to any other
- AR experiences have no awareness of the environment around them
- No way to manage it all as one system

6 vendors. 6 separate systems. None connected.

Enterprises can't commit on infrastructure a single company can shut down

Single points of potential failure are not acceptable to many

~~AltspaceVR~~

Shut Down 2023

Community and content lost
overnight

~~HoloLens~~

Discontinued 2024

Enterprises stranded
mid-deployment

~~8th Wall~~

Acquired • Deprecated

Builders forced to start over

~~ReadyPlayerMe~~

Acquired by Netflix

Platform pivoted away from
creators

5 Enterprise Non-Negotiables to Deploy Spatial Services

The spatial computing ecosystem cannot reach enterprise scale without satisfying all five

These are enterprise procurement requirements

6 solutions needed that web browsers & closed platforms don't provide

Self-hosted spatial content

Closed platforms don't allow you to host your 3D content the same way you host a website on your own server. The metaverse browser connects to it directly

Publish 3D content like a website

Closed platforms don't allow you to drop content on a server and the metaverse browser engine retrieves, renders and displays it properly on any device (Mobile, PC, VR, AR)

Proximity-based scene loading

The engine loads content based on where you are. Proximity-based, built in. Relevant content appears automatically as you move

Trusted, unified multi-origin scenes

Independent operators compose one continuous 3D scene together. Each securely isolated from the others, all services in one view

Seamless service integration

Spatial services stream in and out automatically as you move. No stopping to install every service. No per-service setup every 10 feet

Real-time spatial co-presence

AR and VR participants share one space in real time. All devices (including mobile and desktop), one experience

**How can we meet these
requirements?**

Introducing Sneeze

The first open metaverse browser engine for spatial browsing

Embedded in current web browsers

- Powers standalone metaverse browsers
- Embed directly on XR devices

Open source (Apache 2.0). Built through OMBI under the Metaverse Standards Forum

Sneeze delivers spatial browsing

The reach of the web, the power of native apps, all in one engine.

The Web

Multi-device deployment

Instant access, no installs

URL-based navigation

Open standards ecosystem

Sneeze

Spatial browsing

Multi-origin composition

GPU-native rendering

Content-first development

Native Engines

(Unity, Unreal, etc.)

High-performance 3D graphics

Full device access

Large memory and storage

Rich spatial capabilities

Sneeze unifies industry fragmentation

What Sneeze provides

Tangible capabilities the engine brings to the browser

01

Multi-Origin Scene Composition

Compose content from dozens of independent providers into one unified scene

02

Proximity-based Browsing

Connect to spatial services that stream in and out automatically – no installs

03

Spatial Anchoring

Physical and virtual world anchoring
Content loads based on proximity

04

Decentralized Identity

Cryptographic credentials
No per-service sign-on, portable across fabrics

05

Rendering Abstraction

Render to any device from one engine
(phone, AR glasses, VR headset, desktop)

06

Co-Presence

AR and VR participants share one space in real time – all devices, one experience

07

Certificate-Based Security

Signed certificates replace domain-based security as the basis for trusted multi-origin composition

Focus on your content. The browser handles the rest.

With Sneeze, you publish spatial content and the engine handles delivery, rendering, and display on any device.
Just like the web.

What Sneeze provides

Tangible capabilities the engine brings to the browser

01

Multi-Origin Scene Composition

Compose content from dozens of independent providers into one unified scene

02

Proximity-based Browsing

Connect to spatial services that stream in and out automatically – no installs

03

Spatial Anchoring

Physical and virtual world anchoring
Content loads based on proximity

04

Decentralized Identity

Cryptographic credentials
No per-service sign-on, portable across fabrics

05

Rendering Abstraction

Render to any device from one engine
(phone, AR glasses, VR headset, desktop)

06

Co-Presence

AR and VR participants share one space in real time – all devices, one experience

07

Certificate-Based Security

Signed certificates replace domain-based security as the basis for trusted multi-origin composition

Four key innovations to make an open metaverse possible

Scene Object Model (SOM)

Connected Services update a shared 3D scene graph in real time. The browser connects to and composes from multiple origins – no third-party platform or app needed.

Spatial Fabrics

A spatial fabric is the evolution of a website – a 3D map with anchored content and embedded services. It tracks user proximity relative to available services and offers connection.

RMAP

RMAP links the browser engine to spatial fabric services. Portable, performant, and robust service discovery and connection.

Certificate Based Security

The web uses domain names for security, where Sneeze uses signed certificates for spatial fabrics which makes the SOM possible

Every concept that makes the web work has a direct metaverse equivalent

The Web		The Metaverse
 Web Server A server that hosts a website	→	 Metaverse Server A server that hosts a spatial fabric
 Website A page served from one origin	→	 Spatial Fabric A 3D environment hosted by one operator
 Web Browser Chrome, Firefox, Safari	→	 Metaverse Browser Any browser built with a Metaverse Browser Engine
 Browser Engine Blink, Gecko, WebKit	→	 Metaverse Browser Engine Sneeze
 HTTP / HTTPS Protocol connecting browser to web server	→	 RMAP (REST, WebSocket, Other) Protocol connecting browser to metaverse server
 DOM (Document Object Model) 2D document tree representing a page	→	 SOM (Scene Object Model) 3D graph representing a collection of spatial fabrics
 URL / Web Address Navigate explicitly by typing an address	→	 Proximity + URL Content loads as you approach

Spatial Fabric

A mapped coordinate space containing content and services

The evolution of a website

Hosted on a metaverse server • Accessed by proximity

Spatial Fabrics: The metaverse equivalent of a website

Content and Services

glTF • USD • GeoPose

Composable

Many fabrics, content & services

Proximity Based

Enter a location to connect

Services + RMAP: Software embedded on spatial fabrics

Services are pieces of software embedded on spatial fabrics, from any provider.
RMAP connects to metaverse servers that host them

Embedded on Spatial Fabrics

Anchored to location in a scene

Self or 3rd-Party Hosted

Any provider can publish

No Installs

It works like visiting a website

This is what makes a metaverse browser different

How does the SOM work?

No app installs. 3 operators. 3 independent services. 1 continuous scene.

Each company hosts its own spatial fabric, controls its own data, and the metaverse browser composes them all — securely isolated

RP1 introduces the first *native* metaverse browser using Sneeze
